Modules and Architecture

vga_top - connects all modules and finalizes the architecture

fsm - manages the logic for moving on the screen, based on inputs and vertical sync

img_gen - renders a rectangle, colors switching and background

vga_sync - generates horizontal and vertical timing signals for 640x480 display

debounce - ensures one physical press equals exactly one clean digital signal

clk_en - transforms system clock into a periodic pulse, tells other modules when to perform an action

I/O and controls

btnd - moves the square down along the Y-axis

btnd - moves the square up along the Y-axis

btnd - moves the square left along the X-axis

btnd - moves the square right along the X-axis

btnc - instantly resets the square's position to the center of the screen

sw_red[0] - physical switch on the board, changes the color of the rectangle

sw_chess[15] - changes the color of background

clk - the main system clock that drives all synchronous logic in the design

vga_xsync - tells the monitor to go back to the left edge of the screen, it's also used to move to the next row of pixels once per line

vga_ysync - tells the monitor to go back to the top of the screen, it's also used to update the animation once per frame

vga_r/g/b - physical pins sending analog color data to the VGA port

What does it display?

It displays a rectangle which can be moved based on the controls. We can switch the colors of the rectangle by turning on/off switches. Where the last switch changes the background to a chess pattern.
